Dopamine receptors are a class of G protein-coupled receptors that are prominent in the vertebrate central nervous system. Dopamine receptors activate different effectors through not only G-protein coupling, but also signaling through different protein interactions. The neurotransmitter dopamine is the primary endogenous ligand for dopamine receptors. Dopamine receptors are implicated in many neurological processes, including motivation, pleasure, cognition, memory, learning, and fine motor control.

A dopamine agonist is a compound that activates dopamine receptors. There are two families of dopamine receptors, D2-like and D1-like, and they are all G protein-coupled receptors. D1- and D5-receptors belong to the D1-like family and the D2-like family includes D2, D3 and D4 receptors. Dopamine agonists are used in Parkinson ' s disease and, to a lesser extent, to treat depression, hyperprolactinemia and restless legs syndrome.

Dopamine agonist - Wikipedia

An "agonist" is a medication that binds to and activates receptors in your body (in this case, your dopamine receptors). Common dopamine receptor agonists include ropinirole, cabergoline, bromocriptine, pramipexole, and rotigotine, among others. Depending on the medication and your needs, they may be prescribed as capsules, patches, or injections.
